

## Heat Exchanger Simulation

Example 1: 47200 kg/hr. of process condensate with operating pressure of 1.5 barg and operating temperature of 100C should be cooled to 65C. Using Aspen Hysys, calculate the duty of the heat exchanger used for such application.

How to simulate:

## 1.Add water in component list

Source Databank: HYSYS

Select: **Pure Components** Filter: **All Families**

Search for: Search by: **Full Name/Synonym**

Component	Type	Group
H2O	Pure Component	

< Add Replace Remove

Simulation Name	Full Name / Synonym	Formula
Methane	C1	CH4
Ethane	C2	C2H6
Propane	C3	C3H8
i-Butane	i-C4	C4H10
n-Butane	n-C4	C4H10
i-Pentane	i-C5	C5H12
n-Pentane	n-C5	C5H12
n-Hexane	C6	C6H14
n-Heptane	C7	C7H16
n-Octane	C8	C8H18
n-Nonane	C9	C9H20
n-Decane	C10	C10H22

Status: OK

## 2.Select NBS as Fluid Package

Set Up | **StabTest** | Phase Order | Notes

6. Based on the result, the cooling duty required is  $6.935 \times 10^6$  kJ/h.

Example 2: Regarding the first example, calculate the exact value of cooling water needed. Cooling water has an inlet temperature of 38C and outlet temperature of 48C. The operating pressure is 4.5 barg and consider 0.6 pressure drop throughout the heat exchanger.

How to simulate:

1. Define Cooling Water stream and for the Hot Medium which should be cooled from 100C to 65C, copy paste it from last simulation.

We don't know about the flowrate of cooling water, so for now we start with 10000 kg/hr.

2. Select a heat exchanger from Model Palette/Heat Exchanger and connect these streams to the heat exchanger. In order to increase water velocity, cooling water passes through tubes. Also, we define Heated Cooling Water and Cooled Hot Medium as the outlet stream.

Under Design/Parameter specify 0.1 bar and 0.6 bar as the pressure drop of shell-side and tube-side respectively. As shown in the Parameter sheet, there are different types of heat exchanger model. Since no phase change is encountered in this simulation, simple end point is applied. Otherwise, simple weighted should be applied.

Remember we have two specs here, the first one being the outlet temperature of Hot medium to reach 65C and the second one, the cooling water outlet temperature to be 48C but the first one is more important.

So here at first, we specify that the hot medium outlet temperature should be 65C and then what the outlet temperature of cooling water is. If it is more than 48C then we increase the flow rate, if it is less than 48C, then we decrease the flowrate.

The outlet temperature is 46.3C. Our spec was 48C. Based on these two trials, we know that the cooling water flowrate should be between 100000 kg/hr. and 200000 kg/hr. since  $46.3 < 48 < 54.6$ .

To find the exact value, Adjust could be used. Our adjusted variable is cooling water flowrate in the stream Cooling Water and our target variable is outlet temperature of hot medium in Cooled Hot Medium, which should be 65C. Also, it should be assumed that the outlet temperature of cooling water should be 48C.

So, we need 166000 kg/hr. of cooling water to have the outlet temperature of 65C.

Example 3: In a process plant, it is decided to re-use a distillation column bottom which is approximately 100 % water, for a packed bed as washing water. The operating temperature is 48C. A typical rule in process engineering is that when a stream temperature is between 130-150C or generally more than 65C, an air-cooled heat exchanger is used. Note that on special cases, water-cooled might be used like previous example.

The hot water flowrate is 8187 kg/hr. The air-cooled heat exchanger is supposed to reduce wash water temperature from 149 to 65C and for cooling down more, a water-cooled heat exchanger is used. Determine how many fans are needed, provided that the maximum temperature of heated air reaches 48C.

How to simulate:

1. Define Wash Water stream like below:

Material Stream: Wash Water
